Background

- Colorectal cancer (CRC) is the 3rd most common and the 2nd most fatal cancer in the world.
- Colonoscopy and guaiac fecal occult blood test (gFOBT; a non-invasive method) are currently used for screening of CRC in Austria.
- Gut microbiota were shown to be dysregulated in gut diseases, including CRC. Thus, microbiome composition has a high potential for employment in the diagnosis and treatment of CRC.
- Machine learning (ML) algorithms have the ability to build a model on training data and use it to make predictions about unknown data. The aims of this study were to identify microbial signatures of CRC and colorectal adenoma and to optimise ML algorithms for the early screening of CRC based on the stool microbiome.

Figure 1: Mechanisms of colon cancer development¹

Methods

- Meta-analysis dataset was used consisting of amplicon sequence reads from 1786 samples from 4 datasets (739 healthy individuals, 757 CRC and 290 adenoma patients)
- Differential abundance analysis (DAA) was conducted using the MaAsLin2 package (version 1.8.0, R version 4.1.2) to identify microbial biomarkers of CRC and colorectal adenoma
- Machine learning (ML) pipeline was written in Python using the sklearn library. 80% of the dataset was used for training and validation and 20% for testing.
- Following parameters have been evaluated to find the best performing model:

Taxonomy level

- species
- genus

Feature selection

- None
- SelectKBest
- MaAsLin2

Algorithm

- Logistic Regression (LR)
- Least absolute shrinkage and selection operator (LASSO)
- Ridge regression (RIDGE)
- Support Vector Machine with linear kernel (SVM linear)
- Support Vector Machine with radial kernel (SVM)
- Random forest (RF)
- Gaussian Naive Bayes (GNB)
- Light Gradient Boosting Machine (LGBM)
- Elastic net

Results

- DAA of CRC vs. healthy identified 40 differentially abundant taxa ($q < 0.05$, $abs(coeff) > 1.5$) with following taxa commonly detected as intestinal biomarkers of CRC in the literature (red are enriched in CRC, green are enriched in healthy): *Fusobacterium*, *Parvimonas*, *Peptostreptococcus stomatis*, *Porphyromonas*, *Faecalibacterium prausnitzii*, *Lachnospiraceae*.
- DAA of adenoma vs. healthy identified only one bacterial family, *Erysipelatoclostridiaceae* enriched in adenoma samples. This taxon has not been detected in adenoma samples in previous studies.

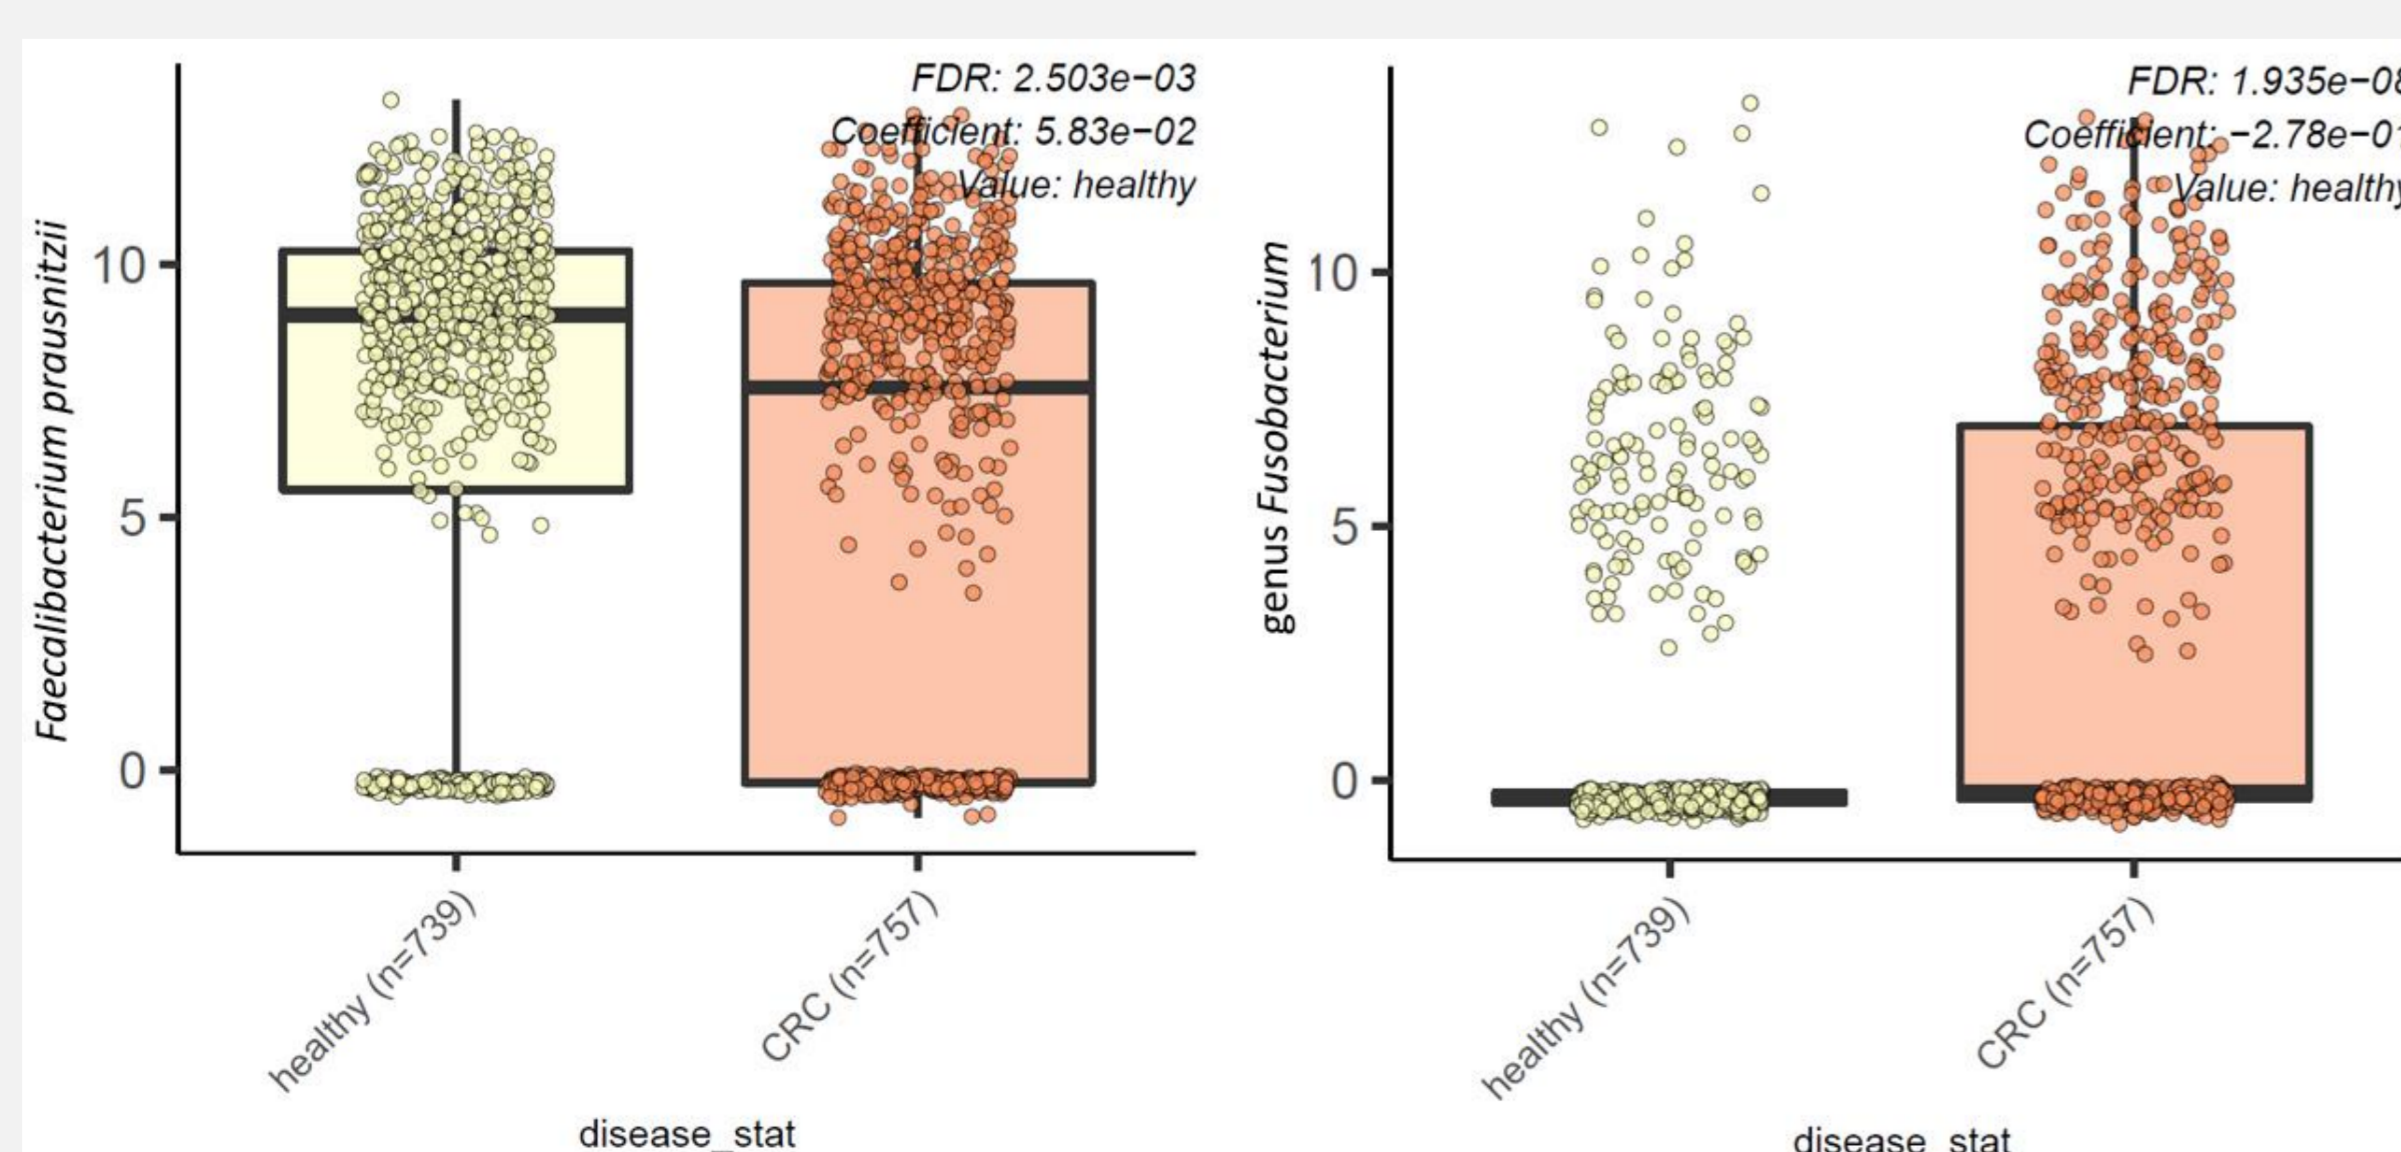

Figure 2: MaAsLin2 plots for two detected differentially abundant taxa; *Faecalibacterium prausnitzii* is enriched in healthy samples and *Fusobacterium* is enriched in CRC samples

- The best performing model for CRC vs. healthy classification was the SVM model on a genus level with MaAsLin2 feature selection method. It resulted in the AUC of **0.843**, sensitivity of **0.724** and specificity of **0.824**.

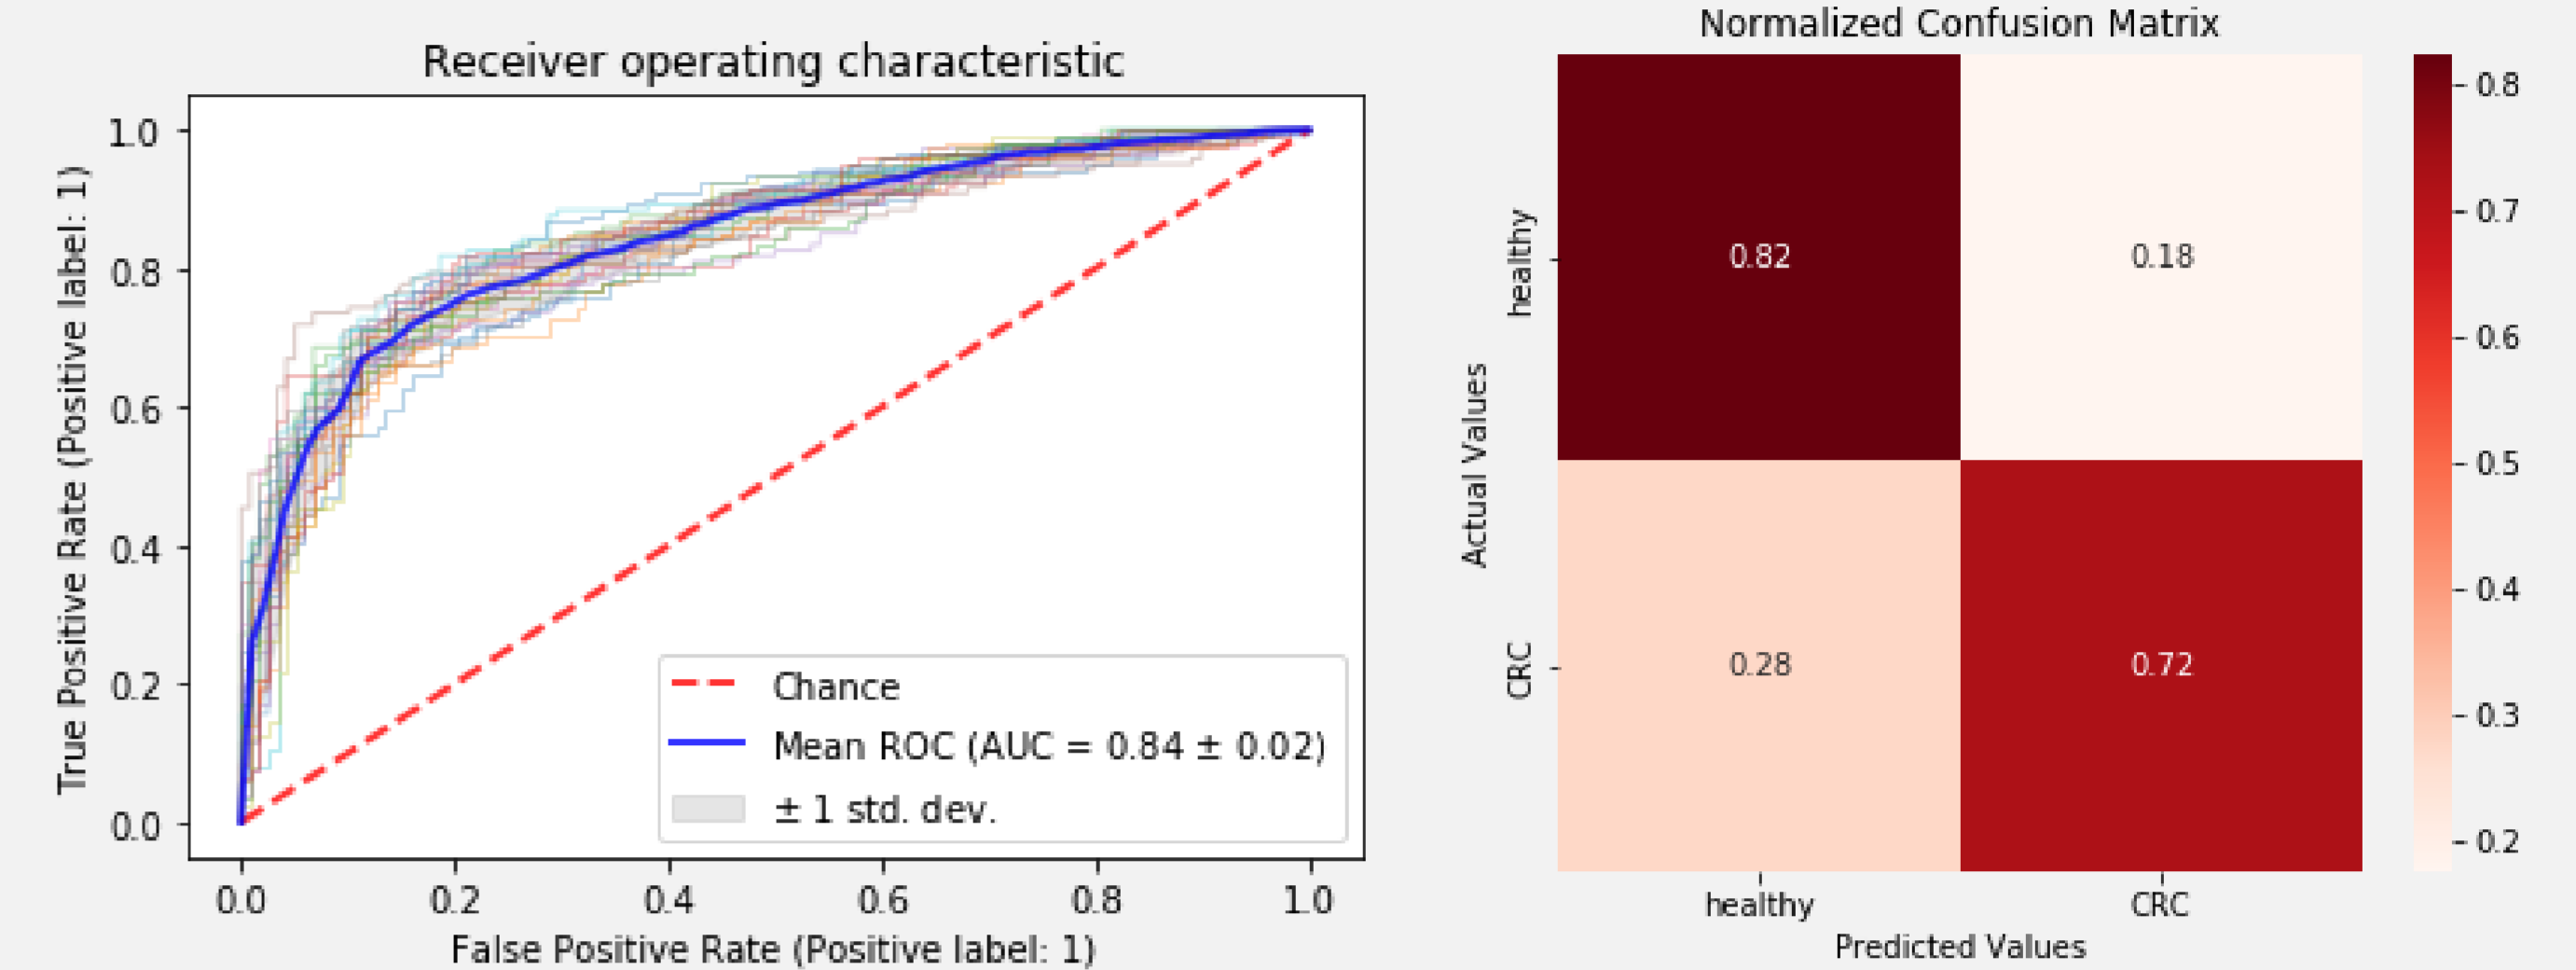

Figure 3: Receiver operating characteristic curve and confusion matrix for the best performing CRC vs. healthy model

- The best performing model for adenoma vs. healthy classification was the LGBM model on a species level with SelectKBest feature selection method. It resulted in the AUC of **0.853**, sensitivity of **0.556** and specificity of **0.852**.

Conclusion

- When compared to other non-invasive methods, the developed ML models are superior to gFOBT at both CRC and adenoma detection and superior to FIT at adenoma detection. Detection at an adenoma stage is crucial for increasing the success rate of the treatment.

- For the first time, a large meta-analysis dataset has been used successfully to demonstrate the suitability of machine learning algorithms for the development of microbiome-based solutions for the non-invasive, early screening of CRC and colorectal adenoma.
